(54) Title: A URO-GENITAL CONDITION TREATMENT SYSTEM

(57) Abstract

The present invention is directed to a system for treating uro-genital conditions. One aspect of this invention involves the treatment system comprising one or more polypeptides with an amino acid sequence including KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), for treatment of uro-genital conditions. The one or more polypeptides can also be a dimer formed from any of the amino acid sequence above. Uro-genital conditions can include infections, inflammation, or both. In one preferred embodiment of the invention, the uro-genital condition includes infection and/or inflammation of the vagina, vulva, urinary tract, penis, and/or the rectum. In another preferred embodiment of the invention, the one or more polypeptides are dissolved in a carrier. In another preferred embodiment of the invention, the one or more polypeptides are associated with a tampon for preventing toxic shock syndrome. In another preferred embodiment, the one or more polypeptides are associated with a contraceptive for prevention of sexually transmitted diseases or infections. In another preferred embodiment, the one or more polypeptides are associated with a suppository for insertion into the vagina or rectum.

SPECIFICATION
A URO-GENITAL CONDITION TREATMENT SYSTEM
PRIORITY CLAIM

The present application is a utility application that claims priority to U.S. Provisional
5 Patent Application Serial No. 60/126,233 entitled Antimicrobial Amino-Acid Sequences
Derived from Alpha-Melanocyte Stimulating Hormone, filed March 24, 1999.

FIELD OF THE INVENTION

The present invention relates to the field of treatment for uro-genital conditions.

BACKGROUND OF THE INVENTION

10 Uro-genital conditions or diseases commonly affect both men and women. These
conditions include infections and/or inflammation of the urinary system and the genital
system. For example, according to the National Institute of Child Health and Human
Development (NICHD), "most women will have at least one form of vaginitis in their
lifetime." Vaginitis, *National Institute of Child Health and Human Development -*
15 *Publications On-line*, (last modified January 12, 2000),
<<http://www.nichd.nih.gov/publications/pubs/vag1.htm>>. The causes for vaginitis range from
bacterial, fungal, or viral infections to irritations from chemicals in creams, sprays, or even
clothing that are in contact with this area. Id. For women with bacterial and fungal
infections, these infectious agents often originate from the rectal area and migrate across the
20 perineum to reach the vagina or the urethra.

A common type of vaginitis is candidiasis or yeast infection that is most commonly
caused by *Candida albicans*. The *Candida* species are part of an individual's normal flora of
microbial organisms present in skin, mouth, and the gastrointestinal tract. *Robbins*
Pathologic Basis of Disease 5th ed., Saunders Co., Philadelphia (1994) p. 354. They also live
25 in small number in a woman's vagina. They grow best in warm, moist surfaces such as the
vagina or the oral cavity. They are normally non-pathogenic, but when a change in their
environment occurs, such as in response to a woman's hormonal changes in menopause,
pregnancy, or in response to stress, they can overgrow to cause a yeast infection. These
changes can also occur in immunosuppressed or compromised individuals such as people
30 undergoing chemotherapy, taking immunosuppressants, or afflicted with AIDS.

Current treatment for candidiasis includes over the counter drugs with active
ingredients such as butoconazole nitrate (Femstat[®]), clotrimazole (Gyne-Lotrimin[®] and
others), miconazole (Monistat[®] and others), and tioconazole (Vagistat[®]). These drugs are
topically applied in the vagina and break down *Candida's* cell wall. Other similar treatments

include prescription drugs with active ingredients in the same family such as fluconazole (Diflucan[®]), terconazole (Terazol[®]), and ketoconazole (Nizoral[®]).

Although vaginitis has been commonly associated with *Candida*, bacterial vaginosis is actually the most common vaginal infection in women of reproductive age according to the
5 NICHD. Vaginitis, *supra*. Overgrowing of bacteria in the vagina causes bacterial vaginosis much like *Candida*, but the drugs used for its treatment are different.

On the other hand, men can also contract *Candida* infections on their penis involving the glans and the prepuce. Balanoposthitis, a nonspecific infection of the glans and prepuce, is caused by a wide variety of organisms including fungi such as *Candida* and pyogenic
10 bacteria such as *staphylococci*. *Robbins Pathologic Basis of Disease 5th ed.*, Saunders Co., Philadelphia (1994) p. 1008.

Staphylococci are gram positive bacteria that are normally present in skin and other mucosal membranes of the body. *Staphylococcus aureus*, in particular, is a virulent pathogen that causes a myriad of conditions and diseases stemming from skin lesions, endocarditis,
15 respiratory infection, food poisoning, to toxic shock syndrome. For women using highly absorbent tampons, it is known that *S. aureus* can colonize the vagina and secrete a toxin called toxic shock syndrome toxin (TSST-1). According to the Food and Drug Administration, approximately half of the toxic shock syndrome cases reported today are associated with tampon use during menstruation and usually in young women. Tampons and
20 Asbestos, Dioxin, & Toxic Shock Syndrome, FDA Center for Devices and Radiological Health (July 23, 1999), <<http://www.fda.gov/cdrh/ocd/tamponsabs.html>>.

S. aureus infections are commonly treated with methicillin. Although it is very effective, some strains of *S. aureus* have developed resistance to methicillin, and only a few antibiotics can successfully treat these methicillin-resistant *Staphylococcus aureus* (MRSA).
25 One of these antibiotics commonly used for MRSA is vancomycin. A strain of *S. aureus*, however, with reduced susceptibility to vancomycin (VISA) has already been identified. Khurshid, M.A., et. al., Staphylococcus aureus with Reduced Susceptibility to Vancomycin -- Illinois, 1999, *Morbidity and Mortality Weekly Report*, 48(51): 1165-1167 (2000), <<http://www.cdc.gov/epo/mmwr/preview/mmwrhtml/mm4851a1.htm>>. The emergence of
30 antibiotic resistant bacterial strains has created a need for alternative ways to combat bacterial infections.

In addition to infection by fungi and bacteria, viral vaginitis is also common. These infections are most often transmitted through sexual intercourse. Viral vaginitis includes infection by *herpes simplex virus* (HSV) or *human papillomavirus* (HPV). HSV viruses, for

example, replicate in the genital area, which is the site of entrance, and also infect the neurons that innervate the genitals. To avoid the body's immune system, HSV viruses can remain latent in these neurons, and become reactivated in response to environmental conditions such as stress, immunosuppression, irradiation, or viral infection. Current
5 treatments for HSV include drugs such as acyclovir, famciclovir, or valacyclovir.

As for the urinary system, according to the American Medical Association, urinary tract infections (UTIs) are one of the most common disorders prompting a physician visit. Women's Health, Urinary Tract Infections: A Patient's Guide to Treatment, AMA Health Insight, On-Line Health Information for Everyone (last updated October 30, 1998)
10 <http://www.ama-assn.org/insight/h_focus/wom_hlth/uti/uti.htm>. These infections are most often caused by *Escherichia coli*, but can also involve organisms such as *Candida* and *Staphylococci*. Id. These infections can start at the urethra and travel up to the bladder causing cystitis. Ultimately, it can even ascend to the kidneys through the ureters and cause pyelonephritis. Both men's and women's urinary systems can become infected with these
15 microorganisms.

Since uro-genital conditions are not confined to one single cause, current treatments require different drugs to treat specific causes. These causes have to be first identified. Identification requires time, but more so, requires a gynecological examination for women to determine the specific infectious agents or lack thereof.

20 With the increased use of antibiotics and other drugs, microorganisms, such as methicillin-resistant *staphylococcus aureus*, are increasingly developing resistance to currently available drugs. Thus, a continuing need exists for new classes of drugs that can combat the broad spectrum of infectious agents.

SUMMARY OF THE INVENTION

25 The present invention is directed to a system for treating uro-genital conditions. One aspect of this invention involves the treatment system comprising one or more polypeptides with a amino acid sequence including KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV (SEQ. ID. NO. 4) for treatment of uro-genital conditions. The one or more polypeptides can also be a dimer formed from
30 any of the amino acid sequence above. Uro-genital conditions can include infections, inflammation, or both. In one preferred embodiment of the invention, the uro-genital condition includes infection and/or inflammation of the vagina, vulva, urinary tract, penis, and/or the rectum. In another preferred embodiment of the invention, the one or more polypeptides are dissolved in a carrier. In another preferred embodiment of the invention, the

one or more polypeptides are associated with a tampon for preventing toxic shock syndrome. In another preferred embodiment, the one or more polypeptides are associated with a contraceptive for prevention of sexually transmitted diseases or infections. In another preferred embodiment, the one or more polypeptides are associated with a suppository for insertion into the vagina or rectum. In another preferred embodiment of the invention, the one or more polypeptides are dissolved in a liquid carrier for douching the vagina.

BRIEF DESCRIPTION OF THE DRAWINGS

- Figure 1 shows the inhibitory effects of α -MSH and/or its derivatives on the growth of *S. aureus*.

- 15 Figures 5A to 5D show the inhibitory effects of α -MSH and/or its derivatives on *C. albicans* germ tube formation.
- Figure 6 shows the enhanced neutrophil-killing effects of α -MSH and/or its derivatives against *C. albicans*.
- 20 Figure 7, 8, and 9 show the mechanism by which α -MSH and/or its derivatives inhibit the growth of *C. albicans*.
- Figure 10-13 show the inhibitory effects of α -MSH and/or its derivatives on viral replication, expression in chronically infected cells.
- Figure 14 shows the mechanisms by which α -MSH and/or its derivatives inhibit viral replication, expression, and reactivation.
- 25 Figure 15 shows the inhibitory effects of α -MSH and/or its derivatives on viral replication, expression in acutely infected cells.
- Figure 16 shows a representation of the chemical structure of one form of the KPV dimer for use with one aspect of the invention.

GENERAL DESCRIPTION OF THE INVENTION

30 The references cited below are hereby incorporated by reference as if fully set forth herein. The present invention involves a method and system for treating uro-genital conditions with the use of alpha-melanocyte stimulating hormone (" α -MSH") and/or its

derivatives. α -MSH is an ancient thirteen amino-acid peptide (SEQ. ID. NO. 4) produced by post-translational processing of the larger precursor molecule proopiomelanocortin. It shares the 1-13 amino acid sequence with adrenocorticotrophic hormone ("ACTH"), also derived from proopiomelanocortin. α -MSH is known to be secreted by many cell types including

5 pituitary cells, monocytes, melanocytes, and keratinocytes. It can be found in the skin of rats, in the human epidermis, or in the mucosal barrier of the gastrointestinal tract in intact and hypophysectomized rats. See e.g. Eberle, A. N., The Melanotrophins, Karger, Basel, Switzerland (1998); Lipton, J.M., et. al., Anti-inflammatory Influence of the Neuroimmunomodulator α -MSH, *Immunol. Today* 18, 140-145 (1997); Thody, A.J., et.al.,

10 MSH Peptides are Present in Mammalian Skin, *Peptides* 4, 813-815 (1983); Fox, J. A., et.al., Immunoreactive α -Melanocyte Stimulating Hormone, Its Distribution in the Gastrointestinal Tract of Intact and Hypophysectomized Rats, *Life. Sci.* 18, 2127-2132 (1981).

α -MSH and its derivatives are known to have potent antipyretic and anti-inflammatory properties, yet they have extremely low toxicity. They can reduce production

15 of host cells' proinflammatory mediators *in vitro*, and can also reduce production of local and systemic reactions in animal models for inflammation. The "core" α -MSH sequence (4-10) (SEQ. ID. NO. 2), for example, has learning and memory behavioral effects but little antipyretic and anti-inflammatory activity. In contrast, the active message sequence for the antipyretic and anti-inflammatory activities resides in the C-terminal amino-acid sequence of

20 α -MSH, that is, lysine-proline-valine ("Lys-Pro-Val" or "KPV") (SEQ. ID. NO. 1). This tripeptide has activities *in vitro* and *in vivo* that parallel those of the parent molecule. The anti-inflammatory activity of α -MSH and/or its derivatives are disclosed in the following two patents and are hereby incorporated by reference: U.S. Patent No. 5,028,592, issued on July 2, 1991 to Lipton, J.M., entitled Antipyretic and Anti-inflammatory Lys Pro Val

25 Compositions and Method of Use; U.S. Patent No. 5,157,023, issued on October 20, 1992 to Lipton, J.M., entitled Antipreytic and Anti-inflammatory Lys Pro Val Compositions and Method of Use; see also Catania, A., et. al., α -Melanocyte Stimulating Hormone in the Modulation of Host Reactions, *Endocr. Rev.* 14, 564-576 (1993); Lipton, J.M., et.al., Anti-inflammatory Influence of the Neuroimmunomodulator of α -MSH, *Immunol. Today* 18, 140-

Sci.* 741, 137-148 (1994); Fajora, N., et.al., α -MSH Modulates Local and Circulating tumor Necrosis Factor α in Experimental Brain Inflammation, *J. Neurosci.* 17, 2181-2186 (1995); Richards, D.B., et. al., Effect of α -MSH (11-13) (lysine-proline-valine) on Fever in the Rabbit, *Peptides* 5, 815-817 (1984); Hiltz, M. E., et. al., Anti-inflammatory Activity of a COOH-terminal Fragment of the Neuropeptide α -MSH, *FASEB J.* 3, 2282-2284 (1989).

In addition to its anti-inflammatory and anti-pyretic function, one aspect of the present invention involves the anti-microbial or anti-infection activity of α -MSH and/or its derivatives. As described below, α -MSH and/or its derivatives have significant anti-infection uses, including, for example, use in reducing the viability of microbes, reducing the germination of yeast, killing microbes without reducing the killing of microbes by human neutrophils, for treating inflammation associated with microbial infection without reducing microbial killing, increasing the accumulation of cAMP in microbes, and inhibiting the replication and expression of viral pathogens.

- 15 In a preferred embodiment of the invention, these anti-microbial or anti-infection activities are most particularly associated with the C-terminal amino-acid sequence - KPV. This tripeptide, along with α -MSH and its derivatives, are effective over a very broad range of concentrations, including picomolar concentrations that normally occur in human plasma.

As discussed in the background section, uro-genital conditions are not confined to one single cause. Multiple organisms and infectious agents, from bacteria, fungi, to viruses, individually or in combination can cause a wide variety of conditions including vaginitis, vulvitis, urethritis, balanoposthitis, candidiasis, sexually transmitted diseases, and toxic shock syndrome. For treatment of these conditions, α -MSH and/or its derivatives can be applied locally to the site of the infection and/or inflammation by methods known in the art.

25 For example, α -MSH and its derivatives can be dissolved in solutions such as phosphate buffer saline, hyaluronate, methylcellulose, carboxymethylcellulose, or ethanol. Common carriers such as ointment, cream, gel, dissolvable pill, aerosol spray, suppository, liquid solution for douche, or the absorbent material of tampons can carry α -MSH and/or its derivatives as active ingredients for treating uro-genital conditions. These carriers can be applied to the site of the infection or inflammation by an applicator such as syringes or syringe-like apparatus, bandages, catheters, tubes with a plunger, spatula or other types of flat surface applicators, condoms, sponges, diaphragms, tampon applicators, or fingers.

More specifically, the preferred embodiment of the invention is to dissolve α -MSH

and/or its derivatives in a liquid-based carrier. This carrier carrying the solvated α -MSH and/or its derivatives is then stored in a pressurized canister. Upon release of the carrier by a release valve or other mechanisms from the pressurized canister, an aerosol foam is formed and captured into a syringe or a syringe-type apparatus. The syringe is then partially inserted
5 into the vagina and its contents delivered into the vaginal canal. The syringe or syringe-type apparatus and its opening can also be molded to different size, shapes, and lengths to accommodate insertion into different uro-genital areas such as the urethra or the rectum.

Another preferred embodiment of the invention is a suppository that comprises a carrier. This carrier such as a gel or glycerin is solid or semi-solid at room temperature, but
10 melts at body temperature when inserted into the vagina or rectum. This carrier carrying the solvated α -MSH and/or its derivatives are delivered into the site of uro-genital condition when the carrier melts.

Delivering α -MSH and its derivatives to the outside area of the uro-genital area such as the vulva or the glans and prepuce of the penis can be achieved by topically applying a
15 cream, ointment, gel, spray, foam, or balm, the compositions of which are already well known in the art.

In another aspect of the invention, tampons can be treated with α -MSH and/or its derivatives during the manufacturing process. The presence of α -MSH in tampons may inhibit the growth of microorganisms such as *Staphylococcus aureus* that secretes the toxic
20 shock syndrome toxin (TSST-1). The processes for making tampons are already well known in the art. Treatment of the tampon's absorbent material with α -MSH or its derivatives may be accomplished by first soaking the absorbent material in a solution of α -MSH and/or its derivatives. The absorbent material can then be allowed to dry. Alternatively, α -MSH may be sprinkled onto the tampon's absorbent material as dry powder.

25 In another aspect of the invention, α -MSH and/or its derivatives may be delivered to the site of the infection by using contraceptives such as condoms, diaphragms, sponges, or other barrier-type mechanisms used for preventing pregnancy or sexually transmitted diseases. α -MSH and/or its derivatives can be dissolved in the lubricant used in condoms, in the gel or foam used together with the diaphragms, or in any other spermicidal solution used
30 in conjunction with condoms, diaphragms, or sponges.

In another aspect of the invention, α -MSH and/or its derivatives may be dissolved in a liquid for use with a douche. The liquid can be delivered by the douche into the vagina for treating infection and/or inflammation.

The following examples demonstrate the ability and application of α -MSH and its derivatives to combat infection. Methods in microbiology, molecular biology, and cell culture used but not explicitly described in this disclosure have already been amply reported in the scientific literature. These methods are well within the ability of one skilled in the art.

5 The peptides used in the following examples include: α -MSH (1-13) (SEQ. ID. NO. 4), (4-10) (SEQ. ID. 002), (6-13) (SEQ. ID. 003), and (11-13) (SEQ. ID. NO. 1), all of which were N-acetylated and C-amidated, and ACTH (1-39) and (18-39) (CLIP). These peptides were prepared by solid-phase peptide synthesis and purified by reversed phased high performance liquid chromatography. Some examples also include a dimer of the amino acid
10 sequence CKPV (SEQ. ID. NO. 8), which also was N-acetylated and C-amidated (the "KPV dimer"). Figure 16 shows a representation of the chemical structure for this KPV dimer. Dimers can be formed by adding cysteines at the N-termini of any of the above polypeptides and allowing the cysteines of two polypeptides to form a disulfide bond. Both homo-dimers and hetero-dimers can be formed using this method.

15 Statistical significance disclosed in the examples below was analyzed using one-way analysis of variance and the Student's t test. Probability values greater than 0.05 were considered significant.

EXAMPLE I

20 This example illustrates the anti-microbial properties of α -MSH and/or its derivatives against *Staphylococcus aureus*.

 Cultures of *S. aureus* (ATCC 29213) were obtained from the collection of the Department of Microbiology, Ospedale Maggiore di Milano. *S. aureus* (1×10^6 /ml in Hank's balanced salt solution) was incubated in the presence or absence of α -MSH (1-13) (SEQ. ID. NO. 4), α -MSH (11-13) (SEQ. ID. NO. 1), or the KPV dimer at concentrations in the range
25 of 10^{-15} to 10^{-4} M for two hours at 37°C. Cells were then washed in cold distilled water and diluted with HBSS to a concentration of 100 organisms/ml. One-milliliter aliquots were dispensed on blood agar plates and incubated for 24 hours at 37°C. Viability of the microorganisms was estimated from the colonies formed. In another set of experiments, 500 units of urokinase, a *S. aureus* growth enhancer, were also incubated with the bacteria
30 (10^5 /100ml) for four hours at 37°C in a shaking water bath together with the peptides.

 Figure 1 shows that α -MSH (1-13) (SEQ. ID. NO. 4), α -MSH (11-13) (SEQ. ID. NO. 1), and the KPV dimer all inhibited *S. aureus* colony formation. These inhibitory effects occurred over a wide range of concentrations and were significant ($p > 0.01$) with peptide

concentrations of 10^{-12} to 10^{-4} M. Figure 2 shows that α -MSH (1-13) (SEQ. ID. NO. 4) and α -MSH (11-13) (SEQ. ID. NO. 1) at concentrations of 10^{-6} M significantly countered the growth enhancing effect of urokinase. Thus, α -MSH or its derivatives can inhibit the growth of *Staphylococcus aureus*, an agent known to cause toxic shock syndrome associated with tampon use, vaginitis, UTIs, urethritis, and balanoposthitis.

EXAMPLE II

This example illustrates the anti-fungal properties of α -MSH and/or its derivatives against *Candida albicans*.

Clinical isolates of *C. albicans* were also obtained from the collection of the Department of Microbiology, Ospedale Maggiore di Milano. Cultures of *C. albicans* were maintained on Sabouraud's agar slants and periodically transferred to Sabouraud's agar plates and incubated for 48 hours at 28°C. To prepare stationary growth-phase yeast, a colony was taken from the agar plate, transferred into 30 ml of Sabouraud-dextrose broth, and incubated for 72 hours at 32°C. Cells were centrifuged at 1000xg for ten minutes, and the pellet was washed twice with distilled water. Cells were counted and suspended in Hank's balanced salt solution ("HBSS") to the desired concentration. Viability, determined by exclusion of 0.01% methylene blue, remained greater than 98%.

At 1×10^6 /ml in HBSS, these fungi were incubated in the presence or absence of α -MSH (1-13) (SEQ. ID. NO. 4), α -MSH (11-13) (SEQ. ID. NO. 1), or the KPV dimer at concentrations ranging from 10^{-15} to 10^{-4} M for two hours at 37°C. Cells were then washed in cold distilled water and diluted with HBSS to a concentration of 100 organisms/ml. One-milliliter aliquots were then dispensed on blood agar plates and incubated for 48 hours at 37°C. The organism's viability was estimated from the number of colonies formed.

Figure 3 shows that α -MSH(1-13) (SEQ. ID. NO. 4), α -MSH(11-13) (SEQ. ID. NO. 1), and the KPV dimer greatly reduced the ability of *C. albicans* to form colony at concentrations ranging from 10^{-12} to 10^{-4} M ($p < 0.01$ vs. control). Thus, this demonstrates that α -MSH or its derivatives can inhibit the growth of *Candida albicans*, an agent known to cause candidiasis, vaginitis, urethritis, and balanoposthitis.

EXAMPLE III

This example compares the anti-infection activities of α -MSH and/or its derivatives to fluconazole, an established anti-fungal agent.

α -MSH (1-13) (SEQ. ID. NO. 4), (4-10) (SEQ. ID. NO. 2), (6-13) (SEQ. ID. NO. 3), (11-13) (SEQ. ID. NO. 1), ACTH (1-39), (18-39), and fluconazole, at concentrations of 10^{-6}

to 10^{-4} M, were tested against *C. albicans* using the same procedures as in Example II. Figure 4 shows that compared with fluconazole, α -MSH (11-13) (SEQ. ID. NO. 1), (6-13) (SEQ. ID. NO. 3), and (1-13) (SEQ. ID. NO. 4) were most effective against *C. albicans*. Their inhibitory activities were similar to fluconazole at the same molar concentration. In contrast, the "core" α -MSH sequence (4-10) (SEQ. ID. NO. 2), which has behavioral effects but little anti-inflammatory activity, caused approximately 50% inhibition of colony forming units (CFU). Although this inhibitory effect was substantial ($p < 0.01$ vs. control), it was significantly less potent than α -MSH fragments bearing the KPV signal sequence, i.e. α -MSH (6-13) (SEQ. ID. NO. 3) and (11-13) (SEQ. ID. NO. 1) ($p < 0.01$), or the parent molecule α -MSH (1-13) ($p < 0.05$). Figure 4 also shows that ACTH (1-39) and the ACTH fragment (18-39) did not reduce *C. albicans* viability. Even at a higher concentration of 10^{-4} M, which is not shown in the figures, ACTH peptides were likewise ineffective.

Thus, this example demonstrates that α -MSH or its derivatives are as effective as fluconazole in inhibiting *Candida's* growth.

15 EXAMPLE IV

This example illustrates that α -MSH and its derivatives inhibit the germination or germ tube formation of *C. albicans*. Germ tube formation is a significant part of the pathogenesis of *C. albicans* infection. This pathogenesis involves adhesion to host epithelial and endothelial cells and morphologic switching from the ellipsoid blastospore to various filamentous forms, e.g. germ tubes, pseudohyphae, and hyphae. Gow, N.A., Germ Tube Growth of *Candida albicans*, *Curr. Topics Med. Myco.* 8, 43-55 (1997).

C. albicans from stationary phase cultures were washed twice with distilled water and suspended in HBSS to a final concentration of 2×10^6 /ml. Hyphal growth was induced by addition of 10% inactivated horse serum (GIBCO/ BRL, Paisley, Great Britain) to yeast incubated for 45 minutes at 37°C with continuous shaking. Horse serum was then removed by washing cells twice with HBSS, and incubation was further continued for 60 minutes at 37°C in the presence of α -MSH (1-13) (SEQ. ID. NO. 4), (6-13) (SEQ. ID. NO. 3), or (11-13) (SEQ. ID. NO. 1) at a concentration of 10^{-6} M with continuous shaking. The percentage of filamentous cells was evaluated under a light microscope with the aid of a hemocytometer. Experiments were run in triplicates and at least 200 cells were scored. Photomicrographs were taken with a MC100 camera attached to an Axioskop Zeiss microscope.

Figure 5A to 5D show that co-incubation of *C. albicans* with α -MSH (1-13) (SEQ. ID. NO. 4) or (11-13) (SEQ. ID. NO. 1) inhibited germ tube formation induced by horse

serum. α -MSH (1-13) (SEQ. ID. NO. 4) caused 28-32% reduction in the number of filamentous cells while α -MSH (11-13) (SEQ. ID. NO. 1) caused 54-58% reduction.

Although not shown in the figures, α -MSH (6-13) (SEQ. ID. NO. 3) similarly had approximately 50% reduction in the number of filamentous cells. Thus, this demonstrates α -MSH or its derivatives can inhibit one mode of *Candida* pathogenesis by inhibiting its germ tube formation.

EXAMPLE V

Reduced killing of pathogens is a dire consequence of therapy with corticosteroids and other nonsteroidal anti-inflammatory drugs during infection. Stevens, D.L., Could Nonsteroidal Anti-inflammatory Drugs (NSAIDs) Enhance Progression of Bacterial Infections to Toxic Shock Syndrome?, *Clin. Infect. Dis.* 21, 977-80 (1997); Capsoni, F., et al., Effect of Corticosteroids on Neutrophil Function: Inhibition of Antibody-dependent Cell-Mediated Cytotoxicity (ADCC), *J. Immunopharmacol.* 5, 217-30 (1983). This example illustrates that α -MSH and/or its derivatives inhibit the growth of infectious agents without comprising the ability of human neutrophils to combat these infections. This example further shows that α -MSH or its derivatives can actually enhance the ability of neutrophils to kill these infectious agents.

Venous blood (20 ml) from healthy volunteers was anticoagulated with heparin. Neutrophils were then isolated using dextran sedimentation and centrifugation with Ficoll-Hypaque (Sigma Chemical Co., St. Louis, Missouri, USA). Erythrocytes were lysed via hypotonic shock with the resulting neutrophils representing at least 97% of the cell suspension. Cell viability, estimated by trypan blue exclusion, was greater than 98%. Neutrophils were resuspended in HBSS for the experiments.

C. albicans (1×10^6) were opsonized with human AB serum in a shaking water bath for 30 minutes at 37°C. They were then incubated with neutrophils in the presence of medium alone, or medium with α -MSH (1-13) (SEQ. ID. NO. 4) or α -MSH (11-13) (SEQ. ID. NO. 1) in concentrations ranging from 10^{-15} to 10^{-4} M in a shaking water bath for two hours at 37°C. After incubation, the culture tubes were placed on ice to stop growth, and extracellular organisms were washed twice with centrifugation at 1000-x g at 4°C. A 2.5% sodium deoxycholate solution was added to the suspension, and the tubes were shaken for five minutes. Cold distilled water was then added to obtain a suspension of 10^6 cells/ml. Two 1/100 serial dilution in HBSS were made to obtain a final suspension of 100 cells/ml. One-milliliter aliquots were then dispensed on blood agar plates and incubated for 48 hours at

37°C. Colony forming units were counted at the end of the incubation period with experiments running in triplicates and repeated using blood from five different donors.

Figure 6 shows that α -MSH (1-13) (SEQ. ID. NO. 4) and (11-13) (SEQ. ID. NO. 1) actually enhanced neutrophil killing of *C. albicans* when administered at concentrations ranging from 10^{-12} to 10^{-4} M ($p < 0.01$). It shows that this enhanced killing occurred over a very broad concentration range including picomolar concentration, which is equal to the concentration of α -MSH found in human plasma.

Thus, this example demonstrates that α -MSH or its derivatives can simultaneously combat against infection and inflammation, which may also be applied to candidiasis, vaginitis, urethritis, balanoposthitis, or hemorrhoids.

EXAMPLE VI

This example suggests the cellular mechanism by which α -MSH and/or its derivatives exerts its anti-microbial properties in general, and anti-fungal properties in particular.

C. albicans (10^6 /ml), permeabilized with toluene/ethanol, were incubated at 37°C with continuous shaking in the presence or absence of 10^{-6} M α -MSH (1-13) (SEQ. ID. NO. 4), (11-13) (SEQ. ID. NO. 1), or forskolin, an agent known to increase intracellular cAMP. The reactions were stopped after three minutes by the addition of ice cold ethanol. cAMP levels were measured in duplicates using a commercial enzyme immunoassay kit (Amersham, United Kingdom) after extraction via the liquid-phase method according to the manufacturer's instructions. In a related experiment, *C. albicans* were also exposed to dideoxyadenosine (ddAdo, Sigma), a potent inhibitor of adenylyl cyclase, at concentrations of 25, 50, and 100×10^{-5} M for two hours and to α -MSH or its derivatives for two additional hours. The effects of forskolin and ddAdo on the ability of *C. albicans* to form colonies were determined according to the procedures described in Example II.

Figure 7 shows that α -MSH (1-13) (SEQ. ID. NO. 4) and (11-13) (SEQ. ID. NO. 1) enhanced cAMP content in the *C. albicans*. This cAMP increase was of the same order of magnitude as that induced by equimolar forskolin. Figure 8 shows that along with α -MSH (1-13) (SEQ. ID. NO. 4) and (11-13) (SEQ. ID. NO. 1), forskolin also significantly inhibited the growth of *C. albicans* relative to control ($p < 0.01$). Figure 9 shows that ddAdo has the ability to reverse the effect of α -MSH (1-13) (SEQ. ID. NO. 4) and (11-13) (SEQ. ID. NO. 1) on the growth of *C. albicans*.

This example demonstrates that α -MSH and its derivatives most likely inhibit growth of *C. albicans* and other microorganisms by increasing its cAMP level, which in turn inhibits

mRNA and protein synthesis. see e.g. Bhattacharya A., et. al., Effect of Cyclic AMP on RNA and Protein Synthesis in *Candida albicans*, Biochem. Biophysics. Res. Commun., 77: 1483-44 (1977).

EXAMPLE VII

5 This example illustrates the ability of α -MSH or its derivatives to inhibit viral replication in human cells. More specifically, α -MSH inhibited the replication and expression of HIV-1 in chronically infected human monocytes.

 Chronically HIV-1 infected promonocytic U1 cell line is an *in vitro* model of latent HIV infection in monocytes. These cells carry two integrated proviral copies of HIV, and
10 constitutive expression of HIV is very low. Viral replication, however, as measured by RNA transcription, p24 antigen, or reverse transcriptase release, can be activated with different stimuli such as TNF- α , IL-6, IL-10, PMA or crowding of cells.

 To determine the effects of α -MSH and/or its derivatives on HIV replication, these cells were maintained in log phase of growth in complete culture medium (RPMI 1640
15 supplemented with 10mM Hepes), 2 mM L-glutamine (Sigma-Aldrich), 10% heat-inactivated FCS (Hyclone Laboratories, Logan, UT, USA), penicillin at 100 units/ml and streptomycin at 100 μ g/ml (Gibco Laboratories, Grand Island, NY) in log phase of growth. Pilot experiments were first performed to determine optimal cell density, stimuli concentration, and kinetics of HIV-1 p24 antigen production using these culture conditions. Before use, cells were washed
20 three times with HBSS to remove extracellular viruses. Cells were then plated onto 24-well flat-bottomed plates at a concentration of 2×10^5 /ml (final volume of one ml) with medium alone or plus TNF- α (10 ng/ml) (R&D Systems, Oxford, England, UK) in the presence or absence of α -MSH (1-13) (SEQ. ID. NO. 4) or (11-13) (SEQ. ID. NO. 1) in concentrations from 10^{-15} to 10^{-4} M.

25 In further experiments, α -MSH (11-13) (SEQ. ID. NO. 1) alone at 10^{-5} M was added to U1 cells stimulated with TNF- α (10ng/ml), IL-6 (20ng/ml), IL-10 (20ng/ml) (R&D Systems, Oxford, England, UK), PMA (1ng/ml) (Sigma-Aldrich), or in crowding conditions. Crowding was achieved by seeding U1 cells at a density of 2×10^5 /ml and maintaining them in culture at 37°C in 5% CO₂ without changing media for seven days. Cultures activated with
30 cytokines or PMA were maintained for only 48 hours. Supernatants were then removed by centrifugation and assayed for p24 antigen using commercially available ELISA kits from Cellular Products, Inc. in Buffalo, NY, USA. Reverse transcriptase releases were also measured using a commercially available kit, ELISA Retrosys RT assay from Innovagen.

Lund, Sweden. For these experiments, addition of α -MSH (11-13) (SEQ. ID. NO. 1) occurred on day one, and each condition was tested in triplicates.

Figure 10 shows that α -MSH (1-13) (SEQ. ID. NO. 4) and (11-13) (SEQ. ID. NO. 1) significantly inhibited p24 antigen release from TNF- α stimulated U1 cells over a broad range of concentrations. The most effective concentration for both peptides was 10^{-5} M, causing 52.7% and 56.0% inhibition respectively. Figure 11 shows that α -MSH (11-13) (SEQ. ID. NO. 1) also inhibited p24 antigen and reverse transcriptase release from U1 cells induced by IL-6, IL-10, PMA and in crowding condition. In addition, figure 12 shows that α -MSH(11-13) (SEQ. ID. NO. 1) also inhibited the transcription of both spliced and unspliced HIV-1 RNA in PMA stimulated U1 cells as measured by Northern Blot analysis.

Thus, this example demonstrates that α -MSH or its derivatives can inhibit transcription of viral genes through mediation of the TNF- α , IL-6, and IL-10 pathways.

EXAMPLE VIII

This example further illustrates the ability of α -MSH to inhibit viral replication and activation. More specifically, the addition of a neutralizing antibody to α -MSH in U1 cells substantially increased p24-antigen release.

U1 cells were cultured similarly as described in Example VII. Endogenous α -MSH produced by U1 cells was blocked with an affinity purified rabbit-anti- α -MSH antibody (Euro-Diagnostica, Malmo, Sweden) diluted 1:250 with medium. Control antibody was a rabbit IgG at the same dilution. Cells (2×10^5 /ml) treated with the anti- α -MSH or the control antibody was coincubated with medium or PMA (1ng/ml). After 48-hour incubation at 37°C, supernatants were separated and tested for p24 antigen release. In crowding experiments with U1 cells cultured as described above, the anti- α -MSH antibody or the control IgG was added on day one and the supernatants were harvested on day seven.

Figure 13 shows that blocking α -MSH in resting, PMA induced, or crowded U1 cells significantly increased the release of p24 antigen. This example strongly implies that viral replication is affected by α -MSH.

EXAMPLE IX

This example illustrates the mechanism by which α -MSH and/or its derivatives inhibit viral replication and expression. More specifically, α -MSH or its derivatives inhibited TNF- α induced NF- κ B activation and binding.

To determine the level of NF- κ B activity, nuclear extracts were prepared from 20×10^6 U1 cells (2×10^5 /ml in complete medium) stimulated for four hours with TNF- α (20ng/ml) in the presence or absence of 10^{-5} M α -MSH (11-13) (SEQ. ID. NO. 1). Cells were washed once with cold PBS, and twice with buffer A (10mM Hepes pH 7.9, 1.5mM $MgCl_2$, 10 mM KCl, 0.5 mM PMSF and 0.5 mM DTT), centrifuged, and incubated for ten minutes on ice in buffer A plus 0.1% NP-40. Afterwards, the supernatants were removed, and the nuclear pellets were resuspended in 15 μ l of buffer C (20mM Hepes pH 7.9, 1.5mM $MgCl_2$, 0.42 M KCl, 0.2mM EDTA, 25% glycerol, 0.5mM PMSF, and 0.5mM DTT), incubated for 15 minutes on ice, mixed, and then centrifuged. The supernatants were diluted with 75 μ l of modified buffer D (20 mM Hepes, pH 7.9, 0.05 mM KCl, 0.2mM EDTA, 20% glycerol, 0.5 mM PMSF, and 0.5mM DTT) and stored at -80°C. The binding reaction was carried out for fifteen minutes at room temperature with 10 μ g of nuclear extract protein and 0.5 ng of 32 P-labelled NF- κ B (30,000 cpm/ μ l) or AP1 consensus in buffer A (12 mM Tris-HCl pH 7.8, 60 mM KCl, 0.2 mM EDTA, 0.3 mM DTT), plus 10% glycerol, 2 μ g/ml bovine serum albumin and 1 μ g/ml single stranded DNA (Pharmacia Biotech). The oligonucleotides for NF- κ B used in these studies were : + GAT CCA AGG GGA CTT TCC GCT GGG GAC TTT CCA TG, and - GAT CCA TGG AAA GTC CCC AGC GGA AAG TCC CCT TG. Each oligonucleotide was annealed to its complementary strand and end-labeled with 32 P- γ -ATP using polynucleotide kinase. For the determination of specific bands, nuclear extracts were first incubated with 100 fold excess unlabeled probe for five minutes, before incubation with a labeled probe. The mixtures were then run on 5% (30:1) acrylamide gel in 1x TBE. The gels were dried and autoradiographed.

Figure 14 shows that TNF- α greatly enhanced NF- κ B binding activity, but the co-incubation of α -MSH (11-13) (SEQ. ID. NO. 1) at 10^{-5} M significantly reduced NF- κ B activation. α -MSH (11-13) (SEQ. ID. NO. 1), however, did not alter NF- κ B activation in resting cells. This suggests that α -MSH and/or its derivatives inhibit viral replication and expression through regulation of the NF- κ B binding.

Replication of viral agents often depends on the state of activation of infected cells and is often regulated by interactions between viral and host factors. These host factors may include TNF- α and other cytokines such as the interleukins. Similar to HIV-1 infection and activation, herpes simplex virus also become reactivated from latency in response to host cytokines. For example, TNF- α and IL-6, but not IL-1 and IL-3, have been shown to

- reactivate HSV infection. Neutralization of IL-6 with antibody against IL-6 significantly inhibited HSV reactivation while neutralization of interferon alpha and beta did not. see e.g. Baker, M., et. al., The Relationship between Interleukin-6 and Herpes Simplex Virus Type-1: Implications for Behavior and Immunopathology, Brain Behav. Immun. 13(3):201-11 (1999);
- 5 Noisakran S., e. al., Lymphocytes Delay Kinetics of HSV-1 Reactivation from in vitro Explants of Latent Infected Trigeminal Ganglia, J. Neuroimmunol. 95(1-2):126-35 (1999);
- Walev, I., et.al., Enhancement by TNF-alpha of Reactivation and Replication of Latent Herpes Simplex Virus from Trigeminal Ganglia of Mice, Arch Virol. 140(6):987-92 (1995);
- 10 Domk-Optiz, I., et. al., Stimulation of Macrophages by Endotoxin Results in the Reactivation of a Persistent Herpes Simplex Virus Infection, Scand J. Immunol. 32(2):69-75 (1990); Fauci, A.S., Host Factors in the Pathogenesis of HIV-induced Disease, Nature 384: 529 (1996).

TNF- α or infection by viruses, including HSV, can cause targeted destruction of I κ B, which in turn activates the nuclear translocation of NF- κ B. Nuclear translocation promotes NF- κ B binding to DNA operators for the transcription of a range of inflammatory agents

15 including TNF- α , IL-6, and other cytokines. The expression of these cytokines, again, further reactivates other HSV infected cells to produce HSV viruses. see e.g. Patel, A., et. al., Herpes Simplex Type 1 Induction of Persistent NF- κ B Nuclear Translocation Increases the Efficiency of Virus Replication, Virology 247(2):212-22 (1998).

Thus, by blocking NF- κ B binding, α -MSH and/or its derivatives inhibit the

20 expression of more inflammatory cytokines that can reactivate HSV. This example and Examples VII-VIII show that α -MSH and/or its derivatives inhibit viral replication, expression, and reactivation by inhibiting NF- κ B binding in response to the body's cytokines or other viral infection.

EXAMPLE X

25 This example illustrates the ability of α -MSH and/or its derivatives to inhibit viral replication in acutely infected human cells. More specifically, α -MSH inhibited the replication and expression of HIV-1 in acutely infected human peripheral blood mononuclear cells (PBMCs).

PBMCs were isolated from normal donors by Ficoll-Hypaque density gradient

30 centrifugation. Monocytes were isolated by Percoll gradient separation and allowed to differentiate into macrophages (MDM) in complete medium of RPMI plus 20% FCS using 24-well tissue culture plates at 10^6 cells/ml for seven days. MDM were infected with monocyctotropic HIVBa-l strain (1:10) overnight. The undiluted viral stock contained 10^7

infectious units/ml. After 24 hours, MDM were washed and resuspended in complete medium, replaced three times a week, for three weeks. Reverse transcriptase releases were measured weekly post-infection using a commercially available kit, ELISA Retrosys RT assay from Innovagen, Lund, Sweden. 10^{-5} M α -MSH (11-13) (SEQ. ID. NO. 1) was added at the time of HIV infection and daily until harvests.

Figure 15 shows that α -MSH significantly inhibited reverse transcriptase release in acutely infected MDM. This inhibitory effect was more pronounced on day six but was still statistically significant on day 21.

Thus, this example demonstrates that viral replication at the site of infection can be inhibited by α -MSH or its derivatives. Consequently, the sexual transmission of venereal diseases in general, and HIV in particular can be inhibited by associating α -MSH and/or its derivatives with contraceptives such as condoms, diaphragms, or sponges used during sexual contact, and/or the post sexual contact application of suppositories, cream, ointment, gel, or aerosol foams containing α -MSH and/or its derivatives

15 EXAMPLE XI

This example illustrates the biological functional equivalents of α -MSH and/or its derivatives.

Although specific amino acid sequences described here are effective, it is clear to those familiar with the art that amino acids can be substituted or deleted without altering the effectiveness of the peptides. Further, it is known that stabilization of the α -MSH sequence can greatly increase the activity of the peptide and that substitution of D-amino acid forms for L-forms can improve or decrease the effectiveness of the peptides. For example, a stable analog of α -MSH, [Nle⁴,D-Phe⁷]- α -MSH, which is known to have marked biological activity on melanocytes and melanoma cells, is approximately ten times more potent than the parent peptide in reducing fever. Further, adding amino acids to the C-terminal of α -MSH(11-13) (SEQ. ID. NO. 1) sequence can reduce or enhance antipyretic potency. Addition of glycine to form the 10-13 sequence (SEQ. ID. NO. 5) slightly decreased potency; the 9-13 sequence (SEQ. ID. NO. 6) was almost devoid of activity, whereas the potency of the 8-13 sequence (SEQ. ID. NO. 7) was greater than that of the 11-13 sequence (SEQ. ID. NO. 1). It is known that Ac-[D-K11]- α -MSH 11-13-NH₂ has the same general potency as the L-form of the tripeptide α -MSH (11-13) (SEQ. ID. NO. 1). However, substitution with D-proline in position 12 of the tripeptide rendered it inactive. see e.g. Holdeman, M., et. al., Antipyretic Activity of a Potent α -MSH Analog, *Peptides* 6, 273-5 (1985). Deeter, L.B., et.

al., Antipyretic Properties of Centrally Administered α -MSH Fragments in the Rabbit, *Peptides* 9, 1285-8 (1989). Hiltz, M.E., Anti-inflammatory Activity of α -MSH (11-13) Analogs: Influences of Alterations in Stereochemistry, *Peptides* 12, 767-71 (1991).

Biological functional equivalents can also be obtained by substitution of amino acids having similar hydrophobic values. Thus, for example, isoleucine and leucine, which have a hydrophobic index +4.5 and +3.8, respectively, can be substituted for valine, which has a hydrophobic index of +4.2, and still obtain a protein having like biological activity. Alternatively, at the other end of the scale, lysine (-3.9) can be substituted for arginine (-4.5), and so on. In general, it is believed that amino acids can be successfully substituted where such amino acid has a hydrophobic score of within about ± 1 hydrophobic index unit of the replaced amino acid.

Furthermore, these modified analogs of α -MSH and/or its derivatives can also form dimers as exemplified by the KPV dimer in Figure 16.

EXAMPLE XII

A woman experiences discomfort in her vagina, vulva, and/or urinary tract. An examination by the physician can include a culture be taken from these area. After determining the cause of the discomfort, including any infection or inflammation, the physician may prescribe an antibiotic, anti-fungal, anti-viral, or anti-inflammation drug where appropriate. In addition, the treatment can include a topical application of pharmacologically effective amounts of α -MSH and/or its derivatives carried in an ointment, cream, gel, dissolvable pill, aerosol spray, suppository, liquid solution for douche, or the absorbent material of tampons. The topical treatment can be applied once or multiple times according to the discretion of the physician until the condition is resolved.

This example, where appropriate at the discretion of the physician, can also be applied to a man who experiences discomfort in his penis, testicles, and/or urinary tract. In addition, this topical application of α -MSH and/or its derivatives may also be achieved without a physician such as use as an over the counter drug.

The preceding Examples I-XII demonstrate the anti-infection activities and uses of α -MSH and/or its derivatives. These data are intended only as examples and are not intended to limit the invention to these examples. It is understood that modifying the examples above does not depart from the spirit of the invention. It is further understood that the examples can be applied on its own or in combination with each other.

WHAT IS CLAIMED IS:

1. A uro-genital condition treatment system comprising:
a carrier;
at least one polypeptide including an amino acid sequence selected from a group
5 consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ.
ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent
of any of the foregoing; and
wherein the carrier carries the at least one polypeptide.
2. The uro-genital condition treatment system of claim 1 wherein the at least one
10 polypeptide includes a dimer formed from any amino acid sequence in the group in claim 1.
3. The uro-genital condition treatment system of claim 2 wherein the dimer is a KPV
dimer.
4. The uro-genital condition treatment system of claim 1 wherein the amino acid
sequence KPV (SEQ. ID. NO. 1), HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV
15 (SEQ. ID. NO. 4) is located at the C-terminal of the at least one polypeptide.
5. The uro-genital condition treatment system of claim 1 wherein the amino acid
sequence KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID.
NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), includes at least one amino acid in the D-
form.
- 20 6. The uro-genital condition treatment system of claim 1 wherein the at least one
polypeptide is N-acetylated or C-amidated or both.
7. The uro-genital condition treatment system of claim 1 further comprises an applicator
for applying the carrier to a site of the uro-genital condition.
8. The uro-genital condition treatment system of claim 7 wherein a part of the applicator
25 is for insertion into the vagina, urethra, or rectum.
9. The uro-genital condition treatment system of claim 1 wherein the uro-genital
condition is an infection, inflammation, or both.
10. The uro-genital condition treatment system of claim 1 wherein the uro-genital
condition includes the presence of bacteria or fungi in a uro-genital area.
- 30 11. The uro-genital condition treatment system of claim 1 wherein the uro-genital
condition includes the presence of a virus in a uro-genital area.
12. The uro-genital condition treatment system of claim 1 the uro-genital condition is
caused by a bacterial infection or a fungal infection or both.

13. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition is caused by a viral infection, bacterial infection, fungal infection, or any combination thereof.
14. The uro-genital condition treatment system of claim 10 wherein the bacteria is a gram-positive bacteria.
15. The uro-genital condition treatment system of claim 10 wherein the bacteria is from the genus of *Staphylococcus*.
16. The uro-genital condition treatment system of claim 10 wherein the bacteria is *Staphylococcus aureus*.
17. The uro-genital condition treatment system of claim 10 wherein the fungi is from the genus *Candida*.
18. The uro-genital condition treatment system of claim 10 wherein the fungi is *Candida albicans*.
19. The uro-genital condition treatment system of claim 11 wherein the virus is a HIV.
20. The uro-genital condition treatment system of claim 11 wherein the virus is HSV.
21. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition is located in a female reproductive cavity or on a genitalia or both.
22. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition is located in the urinary tract.
23. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition is located on a penis.
24. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition is located in a rectal cavity or on a rectal area or both.
25. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition includes vaginitis.
26. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition includes cystitis or urethritis.
27. The uro-genital condition treatment system of claim 1 wherein the uro-genital condition includes balanoposthitis.
28. The uro-genital condition treatment system of claim 1 wherein the carrier is a cream, an ointment, a balm, an aerosol foam, an aerosol spray, or a dissolvable pill.
29. A tampon comprising:
an absorbent material;

at least one polypeptide including an amino acid sequence selected from the group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing; and

5 wherein the absorbent material is associated with the at least one polypeptide.

30. The tampon of claim 29 wherein the at least one polypeptide includes a dimer formed from any amino acid sequence in the group in claim 29.

31. The tampon of claim 30 wherein the dimer is a KPV dimer.

32. The tampon of claim 29 wherein the amino acid sequence KPV (SEQ. ID. NO. 1),
10 HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV (SEQ. ID. NO. 4) is located at the C-terminal of the at least one polypeptide.

33. The tampon of claim 29 wherein the amino acid KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4) includes at least one amino acid in the D-form.

15 34. The tampon of claim 29 wherein the at least one polypeptide is N-acetylated or C-amidated or both.

35. A contraceptive comprising:

a barrier;

a carrier associated with the barrier;

20 at least one polypeptide including an amino acid sequence selected from the group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing; and

wherein the carrier carries the at least one polypeptide.

25 36. The contraceptive of claim 35 wherein the at least one polypeptide includes a dimer formed from any amino acid sequence in the group in claim 35.

37. The contraceptive of claim 36 wherein the dimer is a KPV dimer.

38. The contraceptive of claim 35 wherein the amino acid KPV (SEQ. ID. NO. 1),
HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV (SEQ. ID. NO. 4) is located at the
30 C-terminal of the at least one polypeptide.

39. The contraceptive of claim 35 wherein the amino acid sequence KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4) includes at least one amino acid in the D-form.

40. The contraceptive of claim 35 wherein the at least one polypeptide is N-acetylated or C-amidated or both.
41. The contraceptive of claim 35 wherein the barrier is a condom, a diaphragm, or a sponge.
- 5 42. A suppository comprising:
a carrier;
at least one polypeptide including an amino acid sequence selected from the group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent
10 of any of the foregoing; and
wherein the carrier carries the at least one polypeptide.
43. The suppository of claim 42 wherein the at least one polypeptide includes a dimer formed from any amino acid sequence in the group in claim 42.
44. The suppository of claim 43 wherein the dimer is a KPV dimer.
- 15 45. The suppository of claim 42 wherein the amino acid sequence KPV (SEQ. ID. NO. 1), HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV (SEQ. ID. NO. 4) is located at the C-terminal of the at least one polypeptide.
46. The contraceptive of claim 42 wherein the amino acid sequence KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV
20 (SEQ. ID. NO. 4) includes at least one amino acid in the D-form.
47. The suppository of claim 42 wherein the at least one polypeptide is N-acetylated or C-amidated or both.
48. A method of treating uro-genital condition comprising:
using at least one polypeptide including an amino acid sequence selected from the
25 group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing.
49. The method of claim 49 further comprising:
locally applying the at least one polypeptide at a site of the uro-genital condition.
- 30 50. The method of claim 49 wherein the local application is achieved through a suppository, a tampon, or a contraceptive.
51. The method of claim 49 wherein the local application is achieved through a cream, an ointment, a balm, a gel, an aerosol foam, an aerosol spray, or a dissolvable pill.

52. The method of claim 48 wherein the at least one polypeptide includes a dimer formed from any amino acid sequence in the group in claim 48.
53. The method of claim 52 wherein the dimer is a KPV dimer.
54. The method of claim 48 wherein the amino acid sequence KPV (SEQ. ID. NO. 1),
5 HFRWGKPV (SEQ. ID. NO. 3), or SYSMEHFRWGKPV (SEQ. ID. NO. 4) is located at the C-terminal of the at least one polypeptide.
55. The method of claim 48 wherein the amino acid sequence KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4) includes at least one amino acid in the D-form.
- 10 56. The method of claim 48 wherein the at least one polypeptide is N-acetylated or C-amidated or both.
57. A method of preventing toxic shock syndrome comprising:
using at least one polypeptide including an amino acid sequence selected from the group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV
15 (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing.
58. The method of claim 57 wherein the toxic shock syndrome is associated with toxic shock syndrome toxin-1 produced by *Staphylococcus aureus*.
59. The method of claim 57 further comprising:
20 locally applying the at least one polypeptide in the vagina.
60. The method of 59 wherein the local application is achieved through a tampon.
61. The method of 57 wherein the at least one polypeptide is associated with a tampon.
62. A method for preventing infection from sexually transmitted diseases comprising:
using a contraceptive together with at least one polypeptide including an amino acid
25 sequence selected from the group consisting KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV (SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing.
63. A method of claim 62 wherein the contraceptive is a condom, a diaphragm, or a sponge.
- 30 64. A method of claim 63 wherein at least one polypeptide is carried by a lubricant present on the condom.
65. A method of treating an antibiotic resistant microorganism comprising:
using at least one polypeptide including an amino acid sequence selected from the group consisting of KPV (SEQ. ID. NO. 1), MEHFRWG (SEQ. ID. NO. 2), HFRWGKPV

(SEQ. ID. NO. 3), SYSMEHFRWGKPV (SEQ. ID. NO. 4), or a biologically functional equivalent of any of the foregoing.
